**ABSTRACT**

**Introduction:** A complete knowledge of root canal morphology is mandatory for the endodontic therapy to be successful.

**Aim:** The purpose of this article is to emphasize on the thorough knowledge of root canal anatomy.

**Methods:** This case report describes the endodontic treatment of maxillary lateral incisor with three root canals which was confirmed using angulated radiographs (mesial and distal).

**Results:** Maxillary lateral incisor with a three root canal configuration rarely reported in the literature. The tooth had one root with three root canals, one individual canal and two canals crossing at the apical third. This case report describes the successful endodontic retreatment of the maxillary left lateral incisors having combination of vertucci type I & type VII root canal morphological system.

**Conclusion:** This case report describes the endodontic treatment of maxillary left lateral incisor with three root canals, with emphasis on rate of occurrence of multiple canals, and the importance of their identification and treatment.

**Keywords:** Endodontic therapy, Radiograph, Unusual anatomy.

**INTRODUCTION**

Successful endodontic therapy of a tooth demands that the dentist should have a thorough knowledge of the root canal morphology, making it mandatory towards thorough radiographic evaluation and diagnosis of the status of the pulp canals as well as the periapical areas. Improper diagnostic protocol may lead to the failure of endodontic treatment. A wide morphological divergence of the root canal systems is known to exist. Maxillary lateral incisor is located in the location of high embryological risk with several anomalies of developmental origin like dens invaginatus, radicular grooves, and talon cusp and peg shaped. Varying number of the root canals in different teeth, their anatomy and interconnections have been studied and reported by several authors. Vertucci has classified morphological patterns of the root canal systems into eight types. Generally, the maxillary lateral incisors have one root canal with one apical foramen (Vertucci type I). However, the occurrence of three root canals with two separate foramina in the maxillary lateral incisors is very rare.

Funato A has reported a case with two root canals and separate apical foramina in the mandibular central incisor. This case report describes the successful endodontic retreatment of the maxillary left lateral incisors having combination of vertucci type I & type VII root canal morphological system. The case was followed up for period of six months. The striking feature of this report however was the presence of three root canals in maxillary lateral incisor teeth which has not been reported earlier to the best of our knowledge.

**CASE REPORT**

A 42 years old lady reported to the Department of Conservative and Endodontic Dentistry, Regional Dental College, Guwahati, with mild pain in the maxillary left lateral incisor since one year. On clinical examination, grade I mobility with discoloration with missing left central incisor has been seen. Radiograph shows periapical pathology in relation to left maxillary lateral with periodontal widening with missing left central incisor. Medical and family history was non-contributory.

A closer observation of the same radiograph revealed two root canals in 21, a rare morphological variation and in the second radiograph with different angulation revealed additional canal in 21 (Figure 2 & 3). The teeth were isolated with rubber dam and access was done by round bur followed by Endo Z bur (Dentsply maillefer).

Careful exploration of the root canals revealed three separate canals, two labially and one palatally has been found. Working length was established radiographically. The canals were prepared using a step back instrumentation technique upto K file number 55 # instruments. A 2% of chlorhexidine and normal saline were alternatively used as irrigants at every change of instruments.

The canals were dried with sterile paper points and were dressed with calcium hydroxide paste (Pulpdent). The access cavities were then temporarily sealed with cavitemp (Ammdent). At 2 weeks follow up as the teeth were asymptomatic, obturation of the root canals were undertaken with laterally condensed gutta-percha using lateral condensation technique (Figure 4). Post obturation radiograph was taken and the access cavities were sealed with IRM. The patient was followed up at regular interval of 1, 3 and 6 months respectively. At 6 months follow up; complete resolution of the periapical pathology was observed. (Figure 5)
DISCUSSION
Overall success of the endodontic treatment is directly dependent on thorough debridement of the root canals and hermetic seal of the obturated materials, thus proper preoperative radiographic evaluation is necessary.

The anatomy of root canal systems dictates the condition under which root canal therapy is carried out and can directly affect its prognosis. Extra root or root canals if not detected are a major reason for failure of this treatment. Incomplete removal of all the irritants from the pulp space may increase the possibility of treatment failure. The main reasons for failure in endodontic treatment of incisors is the inability to detect the presence of a extra root canal, which can then not be prepared and obturated during treatment.

In present case, three root canals with two separate foramina were distinctly observed in the maxillary left lateral incisor. Numerous antimicrobial agents have been recommended as interappointment dressings. Calcium hydroxide paste is a simple and remarkably effective antimicrobial medicament. It has been shown to dissolve necrotic tissue. In the present case, calcium hydroxide (Pulpdent) was used as the intra-canal medicament. At 15 days recall teeth were asymptomatic and thus taken up obturation.

CONCLUSION
Careful radiographic examination of the root canal system is important prior to the root canal preparation, so as to detect and be aware of variations in root canal anatomy, before and during endodontic treatment procedures. Finally, it is also important that the endodontic treatment be reviewed periodically to ensure continuous healing without complications.
